CLAIMS

1. A method for determining the complex impedance $Z(f_{\mathfrak{m}})$ of a non-stationary electrochemical system, characterized in that it comprises the steps of:

setting the system to a selected voltage state and applying a sinusoidal signal of frequency $f_{\rm m}$ thereto,

measuring, immediately after, successive values of the voltage and of the current at regular time intervals ΔT ,

calculating the discrete Fourier transforms of the voltage (E(f)) and of the current (I(f)), the voltage transform being calculated for the sole frequency \mathbf{f}_m of the sinusoidal signal and the current transform being calculated for frequency \mathbf{f}_m and for two adjacent frequencies \mathbf{f}_{m-1} and \mathbf{f}_{m+1} on either side of frequency \mathbf{f}_m , and

calculating the impedance according to the following 15 formula:

$$Z(f_m) = E(f_m) / I * (f_m)$$

20

where I* designates a corrected current such that:

$$\begin{split} & \text{Re}[\text{I*}(f_m)] = \text{Re}[\text{I}(f_m)] - \left\{ \text{Re}[\text{I}(f_{m+1})] + \text{Re}[\text{I}(f_{m-1})] \right\} / 2 \\ & \text{Im}[\text{I*}(f_m)] = \text{Im}[\text{I}(f_m)] - \left\{ \text{Im}[\text{I}(f_{m+1})] + \text{Im}[\text{I}(f_{m-1})] \right\} / 2 . \end{split}$$

2. The method of claim 1, characterized in that it is repeated for a succession of excitation frequencies.
